# Analysis of Returns versus Trading Period 

## SUMMARY

This analysis illustrates how return rates increase as trading timeframes decrease, in the limiting case where each trading decision is always perfect. In this example, the average annual return rate climbed from $1.2 x$ to $73 x$ per year, as the trading timeframe dropped from annually to hourly (including the extended sessions).

## PROCEDURE

A single stock (IBM) was selected for analysis, since it is a reasonable proxy for all high liquidity U.S. stocks. The prior 14 years was selected for the analysis period, since it contains two economic cycles. The methodology was to make a decision to buy or not at the start of every trading period analyzed (year, month, week, trading day, regular-trading-session hour, and extended-session hour); and then go back to cash (yielding $0 \%$ return) at the end of that period. A buy decision is made if the ( $100 \%$ accurately projected) price is going to rise during the trading period. The model shows the limiting case for returns on this trading scenario, since predictions are $100 \%$ accurate, and commissions, bid-ask spread, and slippage are all considered to be zero.

## DISCUSSION / CONCLUSIONS

The results are shown in Figure 1. As expected, there is a steep rise in the return rate as the prediction / trading period gets shorter. Returns go from $2.1 x$ to $22 x$ per year, averaged over this 14 year analysis period, as one goes from weekly trades to regular-trading-session hourly trades. Returns triple again, on average, if pre-market and after-hours trades are included.

On the down side, there are 50x more trading decisions needed to trade hourly on regular + extended market hours than for trading weekly, but the interval over which one has to predict the price change direction shrinks from 1 week to 1 hour.

## IBM Predictive Trading: Compounded Annual Growth Rate (CAGR)

## versus Trading Period

Assuming $\mathbf{1 0 0 \%}$ accurate prediction of price change direction for next Trading Period,
buying stock at the opening of each Trading Period if the price is going to rise during that Trading Period, and then selling it at the closing of each Trading Period, with all proceeds reinvested
(assumes zero commissions, bid-ask spread, and slippage)
